

TIPS FOR PREVENTING CRYSTAL METH OVERDOSES

Safety Tips:

- Try not to use alone.
- Know your tolerance.
Use less or do a test blast first,
especially if you're buying from a new dealer.
- Try to mix your hits yourself so you know what you
are using.
- Try not to mix substances.
- Remember to call 911 right away if someone needs help,
and get someone with training to do CPR if needed.

HIV and Hep C Prevention Tips:

- If you snort drugs, use your own straw or bumper.
- If you smoke drugs, avoid sharing your pipe.
If you do share a pipe, use your own mouth piece.
- If you inject drugs, avoid sharing any equipment
including syringes, filters, cookers, acidifiers,
alcohol swabs, tourniquets and water.
Try to use new equipment each time.

What is Crystal Meth?

Crystal meth belongs to a family of drugs called amphetamines. These are stimulants that make you feel energetic and more mentally alert. They speed up the heart rate and breathing.

Other names for Crystal meth are tina, ice, crank and tweak.

An overdose happens when there are more drugs in the body than it can handle.

Signs of Crystal Overdose

red face

very rapid or
irregular heartbeat

sweating heavily

rapid breathing, and/
or eye movement

aggression, anxiety,
extreme paranoia

hallucinations

fever

shaking or trembling
(jerky body movements)

stroke or heart attack

Someone who is overdosing may not have all of these signs, they may only have one or two.

Stay with the person and keep checking on them. If paramedics are called, give them as much information as possible so they can give the right treatment. If you can't stay, leave a note about the drug the person took and make sure the ambulance can reach them (for example, make sure doors are unlocked).

What to do:

911

Call 911 if the person:

- is having seizures
 - has signs of a heart attack or pains in the chest
 - is not breathing or has shallow breathing (one of the most common signs of overdose is slow or no breathing)
 - is a risk to themselves or others
- A meth overdose can look different. In some people it can lead to hyper agitation followed by cardiac arrest (heart attack). In others it can lead to the person being unresponsive.
 - Encouraging rest is very important but don't force or restrain the person; this can be dangerous. If the person can walk, move them to a quiet space. If they want to walk around, go with them.
 - Apply cool cloths to their neck and forehead, regularly check to make sure they are breathing and have a pulse.
 - If they are not breathing or there is no pulse, get someone with training to perform CPR.
 - If the person is having seizures (convulsions), clear a space so they don't hurt themselves or accidentally get something in their mouth. Keep the person in the recovery position and make sure their head is supported and their airways are clear.

**Chest compressions &
rescue breathing (CPR)**

Recovery position
